ABSTRACT

An electronic voting system is provided that includes at least one voter interface unit associated with network. The voter interface unit is enabled to identify a voter using a disability related communication device coupled to the network, deliver ballot choices to the voter, accept a ballot choice made by the voter, and deliver the ballot choice to a tabulation system. The system may be configured to confirm each ballot selection made by the voter. The system may further include a ballot design database to provide ballot choices and/or a voter registration database. The system may also be configured to enable the voter with an option to connect the voter with a live poll worker, if desired by the voter, at any time when the voter is connected to the system.
